CSC 115 Ubiquitous Computing

Computing will continue to evolve in the coming generations and that could come with potential problems when new applications start to be introduced in the years to come. Moreover, computers have been through a very long journey from beginning in 1943 with the Electronic Numerical Integrator And Computer to the handheld mini-computers (smartphones) that almost anyone on the planet is carrying as of today. Devices also range not only just smartphones but also devices such as laptops, tablets, e-notebooks, and wearable devices like headphones; etc. Consequently, this has pushed for further development of enhanced technology and with that, has caused issues with applications that have come to pass. Hence, new technology in ubiquitous computing could lead to potential problems by describing some applications used in present society and the policies or rights that this new age of technology can tamper with.

Next, new technology in ubiquitous computing could lead to potential problems by describing some of the applications used in present society because they might violate rights to citizens without realizing the effect it has caused. For example, something as simple as a smartphone has access to all kinds of other technologies such as millions of other smartphones and computers. Furthermore, it becomes a problem when that device does exactly what it is supposed to do; gathering information and exposing the device more into the digital world. Depending on the user, and depending on what territories the device reaches, viruses could be gathered, certain privacies could be leaked, and privacies could also be leaked to other users.

In this situation, the biggest problem is the lack of a well functioning security system to protect these ubiquitous devices. Another example can be hardware components; this can vary from supercomputers, lighting systems, sensors, and multiple others. Additionally, as time goes on technology and ubiquitous devices will continue to evolve, being able to accomplish feats not thought of being possible today. However, the issues described actually come from the components of the hardware rather than the application itself. Additionally, these devices are renowned for having low power; it has always been a difficult task for engineers to resolve. As a result, applications have several issues yet are very serious seeing as how it is an ongoing issue and has not been resolved yet.

In conclusion, computing will continue to adapt and evolve in the coming generations and could reach potential problems in the future. New technology in ubiquitous computing could be discussed through applications used in present society. Additionally, there has always been the ongoing issue of a lack of security systems in computing devices which could cause violations in privacy for users and the possibility of important information being leaked. Also, hardware components could lead to issues as well. Again, technology will continue to evolve which can cause the components to become outdated and unusable. The problems that can arise is low power capabilities within applications; which engineers still have not resolved. Consequently, with the continuous development of new issues regarding security systems and power capabilities, the issues will start to be more common than the development of new systems. In turn, this could cause a halt in production for ubiquitous computing and may give society justifiable reasons for outraging to the industries who produce it.
